BACKGROUND A number of researchers have studied risk-factors for sudden death in paediatric hypertrophic cardiomyopathy (paedHCM), but considerably less is known about risk-factors for heart-failure related death in paedHCM.

PATIENTS AND METHODS A Swedish national cohort consisting of patients with paedCM presenting at age <19 years was assembled from all Pediatric Cardiology Centres in Sweden. There were 152 patients, mean follow-up 10.8yrs, in 26% associated with Noonan-spectrum syndrome. 15 patients who died from heart failure were identified; nine in infancy and six died in their teens or later, often with dilating left ventricle. Univariate and multivariate Cox-hazard regression have been used to identify risk-factors for heart-failure related death (CCF-death).

RESULTS Patients with CCF-death were diagnosed at a young age, 0.10 yrs [median; IQR 0.006-6.0], had generalized left ventricular (LV) hypertrophy with a high LV wall-to-cavity ratio both early (0.46 [0.31-0.57]), and at latest follow-up (0.57 [0.33-0.65]). Left atrium-to aortic (LA:ao) ratio was increased already early 1.72 [1.55-1.84]. 83% had definite or probable Noonan-spectrum syndrome, over-represented both in early and late deaths. LV outflow obstruction at rest (LVOTr) was present in 83%, and in addition in the right ventricular outflow (RVOTr) in 55%. On ECG 12-lead amplitude-times-duration product and ECG risk score were high already at diagnosis 3.51 [2.11-3.71] mV.s and 7 [6-10] points respectively. Risk factors significant on univariate analysis were: diagnosis at young age (p=0.010), co-existing Noonan-spectrum syndrome (p=0.004), left-ventricular wall-to-cavity ratio (early: p=0.003; late: p<0.001), increased posterior LV-wall thickness Z-score (p<0.001), LV outflow-tract obstruction at rest (LVOTOr; p<0.001), RVOTOr (p<0.001), and LA:ao ratio at late follow-up (p<0.001), initial 12-lead product (p=0.005), and initial (p=0.025) and final (p=0.016) ECG risk score. On multivariate analysis many, including Noonan-syndrome, are shown to be linked to LVOTOr, leaving as independent risk factors: RVOTr (p=0.013), LVOTOr (p=0.048) and late LA:ao ratio (p=0.017). Furthermore the only therapy that significantly reduced the risk for CCF-death on multivariate analysis was beta-blocker therapy (p=0.030), whereas calcium-blocker therapy had no significant effect (p=0.313).

CONCLUSIONS Patients at high risk of CCF-death can be identified early, and outflow obstruction should be treated vigorously. Treatment should include beta-blockers rather than calcium-blockers.
